2014

CNL, Galway, August 2014

Executive summary

We want to have machine translation that

- delivers **publication quality** in areas where reasonable effort is invested
- degrades gracefully to **browsing quality** in other areas
- shows a clear distinction between these

We do this by using **grammars** and **type-theoretical interlinguas** implemented in **GF, Grammatical Framework**

Executive summary

We want to have machine translation that

- delivers **publication quality** in areas where reasonable effort is invested
- degrades gracefully to **browsing quality** in other areas
- shows a clear distinction between these

We do this by using **grammars** and **type-theoretical interlinguas** implemented in **GF, Grammatical Framework**

Joint work with

translation by **meaning**

- correct
- idiomatic

translation by **syntax**

- grammatical
- often strange
- often wrong

translation by **chunks**

- probably ungrammatical
- probably wrong

The Vauquois triangle

The Vauquois triangle

What is it good for?

publish the content

get the grammar right

get an idea

Who is doing it?

GF in MOLTO

GF the last 15 months

Google, Bing, Apertium

What should we work on?

All!

semantics for full quality and speed

syntax for grammaticality

chunks for robustness and speed

We want a system that

- can reach perfect quality
- has robustness as back-up
- tells the user which is which

We “combine GF, Apertium, and Google”

But we do it all in GF!

The idea is to understand real problems that one would like to solve, and to do it with the standards of the highest quality research. This combines the best features of “applied research” and “basic research.” I’ve always found it productive to look at the details of real problems. Real problems often reveal issues that you wouldn’t think of otherwise.

William A. Woods, ACL Lifetime Achievement Award
The Right Tools: Reflections on Computation and Language
Computational Linguistics 36(4), 2010.

Interlude: SMT

How SMT works

SMT = Statistical Machine Translation

“Lexicon”: **word alignments**

“Syntax”: **n-grams**

Word order: **distortion model**

Word alignments

wine	—	vino	0.7
red		rojo	0.4
		roja	0.2
		rojos	0.2
		rojas	0.1
		tinto	0.001
black		tintos	0.0002
	—		

n-grams (n = 2)

libro rojo	0.01
roja	0.0001
casa roja	0.01
rojos	0.000001
vino rojo	0.001
roja	0.000001
tinto	0.2

Decoding

Selecting the best translation from f to e

$$\hat{e} = \operatorname{argmax}_e p(f|e) p(e)$$

Shannon's noisy channel model (1948)

Decoding in action: word alignments

red	rojo
	roja
	rojos
	rojas
	tinto
wine	vino

Decoding in action: distortion

wine	red
red	rojo
	roja
	rojos
	rojas
	tinto

Decoding in action: n-grams

wine vino

red rojo

roja

rojos

rojas

tinto

Modern version: phrase alignment

red wine	vino tinto	0.99
	vino rojo	0.01

Problems with SMT

When things are far apart ($n > 3$)

Sparse data: a language has 10^6 “words”

Fundamentally random and uncontrolled

Hard to fix bugs

How to do it in GF?

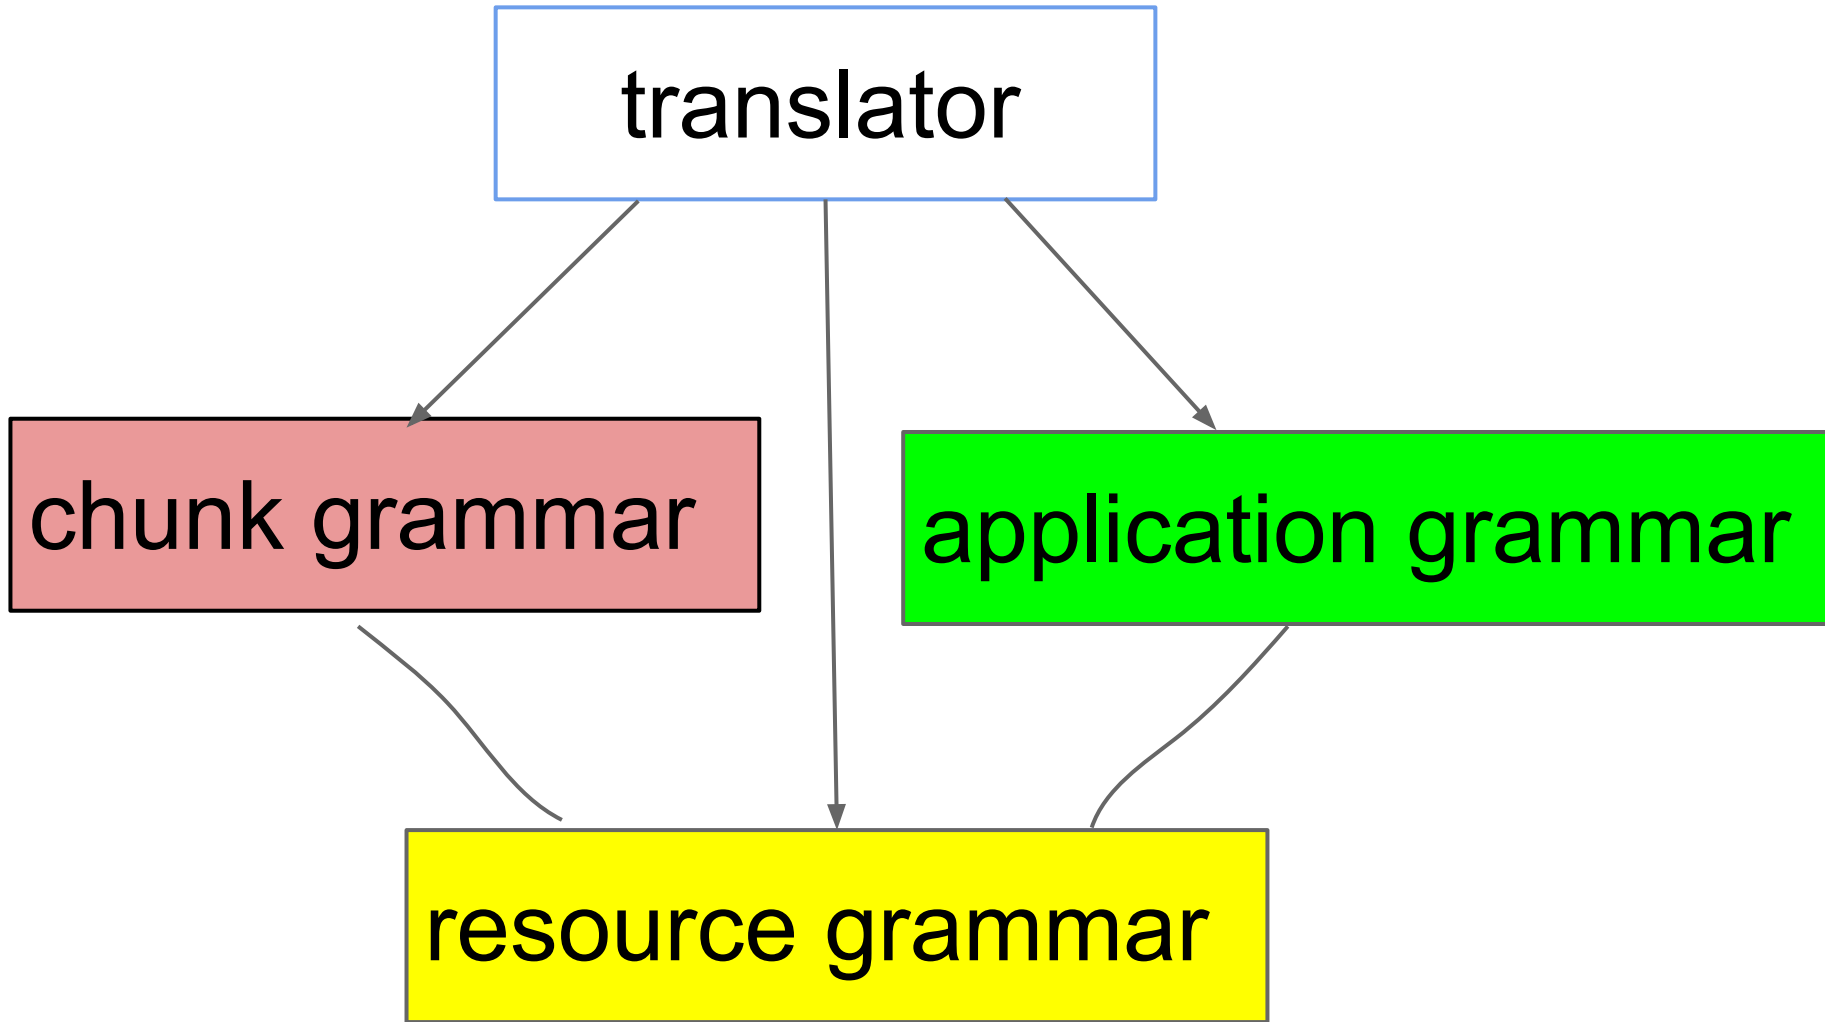

a brief summary

translator

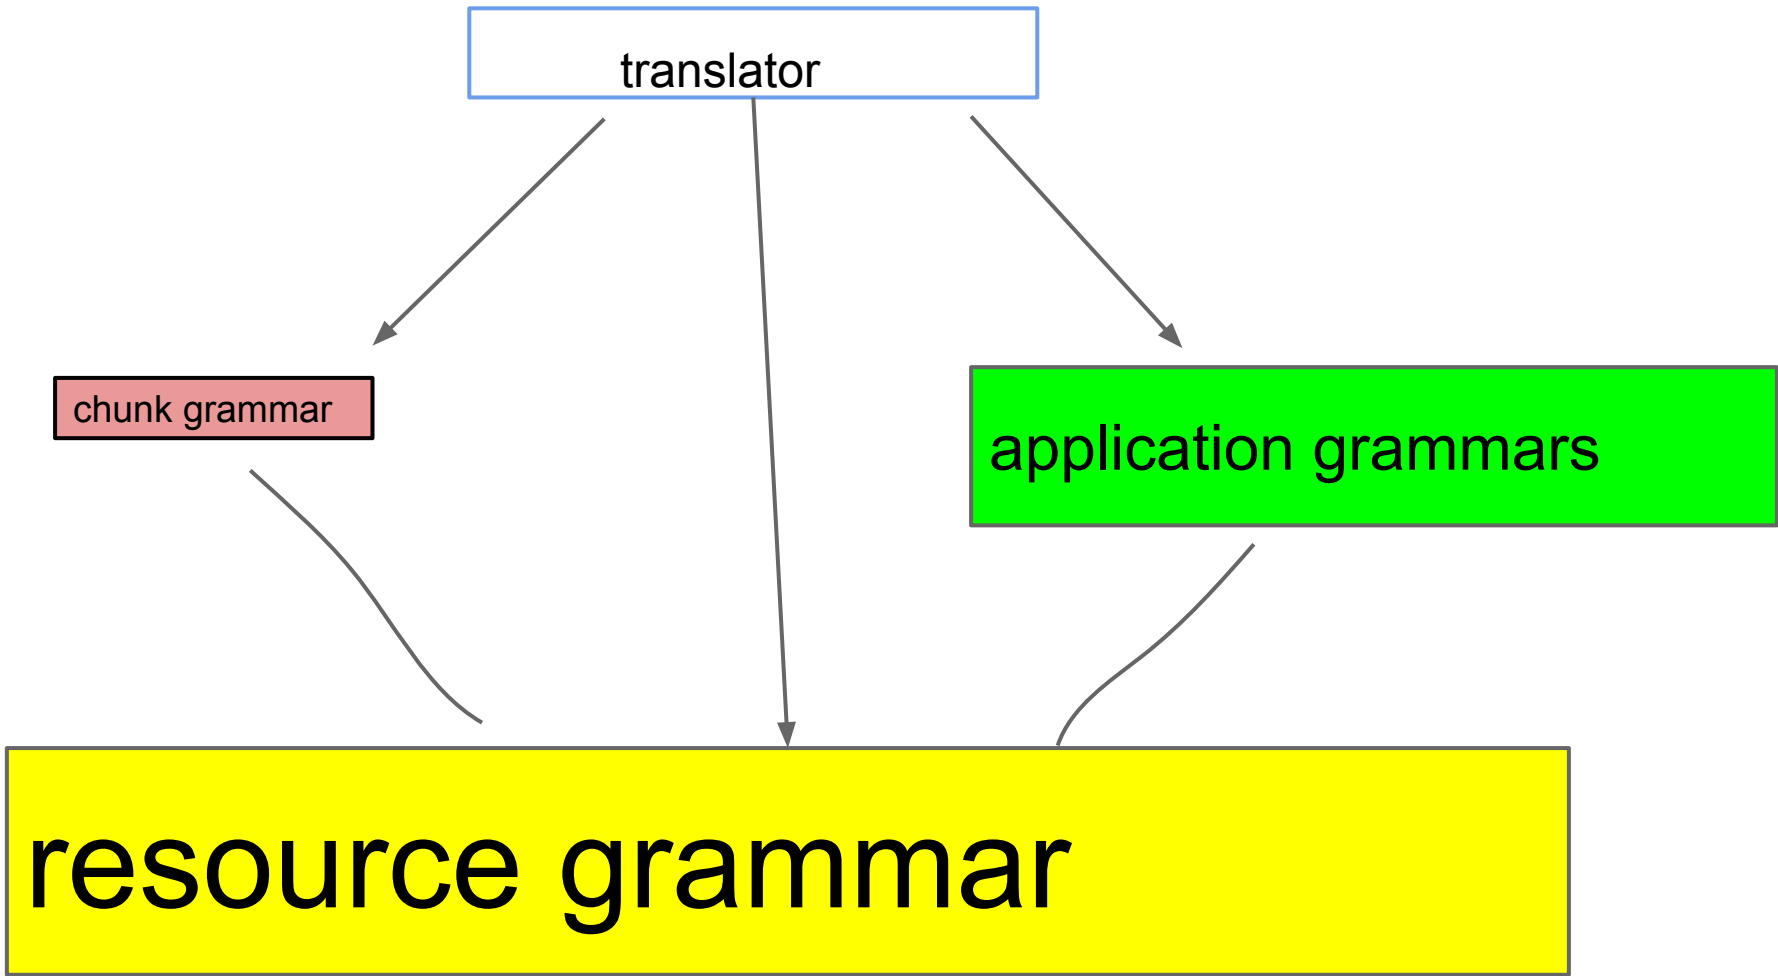

chunk grammar

application grammar

resource grammar

How much work is needed?

resource grammar

- morphology
- syntax
- generic lexicon

precise linguistic knowledge

manual work can't be escaped

chunk grammar

words

suitable word sequences

- local agreement
- local reordering

easily derived from resource grammar

easily varied

minimize hand-hacking

application grammars

domain semantics, domain idioms

- need domain expertise

use resource grammar as library

- minimize hand-hacking

the work never ends

- we can only cover some domains

translator

PGF run-time system

- parsing
- linearization
- disambiguation

generic for all grammars

portable to different user interfaces

- web
- mobile

Disambiguation?

Grammatical: give priority to green over yellow, yellow over red

Statistical: use a distribution model for grammatical constructs (incl. word senses)

Interactive: for the last mile in the green zone

Advantages of GF

Expressivity: easy to express complex rules

- agreement
- word order
- discontinuity

Abstractions: easy to manage complex code

Interlinguality: easy to add new languages

Resources: basic and bigger

Building the yellow part

Building a basic resource grammar

Programming skills

Theoretical knowledge of language

3-6 months work

3000-5000 lines of GF code

- not easy to automate

+ only done once per language

Building a large lexicon

Monolingual (morphology + valencies)

- extraction from open sources (SALDO etc)
- extraction from text (*extract*)
- **smart paradigms**

Multilingual (mapping from abstract syntax)

- extraction from open sources (Wordnet, Wiktionary)
- extraction from parallel corpora (Giza++)

Manual quality control at some point needed

Improving the resources

Multiwords: non-compositional translation

- *red wine - vino tinto*

Constructions: multiwords with arguments

- *x's name is y - x se llama y*

Extraction from free resources (Konstruktikon)

Extraction from SMT phrase tables

- **example-based grammar writing**

It's important to look at the details. Try to understand what would be necessary to solve the whole problem. At this point, don't settle for approximations.

Woods, *ibid.*

Building the red part

1. Write a grammar that builds sentences from sequences of chunks

```
cat Chunk
```

```
fun SChunks : [Chunk] -> S
```

2. Introduce chunks to cover phrases

```
fun NP_nom_Chunk : NP -> Chunk
```

```
fun NP_acc_Chunk : NP -> Chunk
```

```
fun AP_sg_masc_Chunk : AP -> Chunk
```

```
fun AP_pl_fem_Chunk : AP -> Chunk
```

Do this for all categories and feature combinations you want to cover.

Include both long and short phrases

- long phrases have better quality
- short phrases add to robustness

Give long phrases priority by probability settings.

Long chunks are better:

[this yellow house] - [det här gula huset]

[this] [yellow house] - [den här] [gult hus]

[this] [yellow] [house] - [den här] [gul] [hus]

Limiting case: whole sentences as chunks.

Accurate feature distinctions are good, especially between closely related language pairs.

Apertium does this for every language pair.

Resource grammar chunks of course come with reordering and internal agreement

Recall: chunks are just a by-product of the real grammar.

Their size span is

single words <---> entire sentences

A wide-coverage chunking grammar can be built in a couple of hours **by using the RGL.**

If you have a practical job to do, and it's important to get it done quickly as well as possible, and you can only do that by partially solving the problem, then by all means do that. That's practical engineering, and I do that with my Engineer's hat on. But that's not going to advance the science

Woods, *ibid.*

Building the green part

Define **semantically based abstract syntax**

```
fun HasName : Person -> Name -> Fact
```

Define concrete syntax by mapping to resource grammar structures

```
lin HasName p n = mkCl (possNP p name_N) y
```

my name is John

```
lin HasName p n = mkCl p heta_V2 y
```

jag heter John

```
lin HasName p n = mkCl p (reflV chiamare_V) y
```

(io) mi chiamo John

Resource grammars give crucial help

- application grammarians need not know linguistics
- a substantial grammar can be built in a few days
- adding new languages is a matter of a few hours

MOLTO's goal was to make this possible.

Automatic extraction of application grammars?

- abstract syntax from ontologies
- concrete syntax from examples
 - including phrase tables

As always, full green quality needs expert verification

- formal methods help (REMU project)

These grammars are a source of

- “non-compositional” translations
- compile-time transfer
- idiomatic language
- translating meaning, not syntax

Constructions are the generalized form of this idea, originally domain-specific.
